

# Lab 4 — Capstone (Demo Day)

**Demo Day: Thursday, August 27, 2026.** Your exec sponsor and leadership attend to see what you’ve built — this is the formal capstone of the program.

**Deliverable: one real, team-shareable artifact you own** — putting everything from the program to work. **Duration:** self-built through week 6 (office hours + teaming up with other developers); one ~2-hr block at Demo Day. **Surface:** real code — this repo or your own team’s work.

**The challenge.** Pick **one** artifact from the menu, build it on real code, show it working at least once, commit and share it with the team, and present it at Demo Day.

## Pick one artifact

| Artifact                                                                      | Ideas — anything like...                                                                                                  | Build          |
|-------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------|----------------|
| <b>Shareable skill or specialist subagent</b>                                 | things you explain twice: writing tests, drafting PR reviews, debugging a subsystem, scaffolding new code, release chores | solo           |
| <b>Governance / standards contribution</b> — into the team’s Collective Brain | rules that live in someone’s head: naming, what “done” means, which doc to write when, how we work with Claude            | solo           |
| <b>Guardrail / hook bundle</b> — grow your Lab 2 hook into a team policy set  | things reviewers keep catching by hand: protected files, risky commands, architecture rules, secrets                      | solo           |
| <b>Small workflow automation</b>                                              | chores you dread: environment setup, deploy steps, ticket grooming, status reports, form-filling                          | solo or paired |
| <b>MCP server / connector</b>                                                 | systems you keep copy-pasting from: tickets, databases, CI status, internal docs and APIs                                 | solo or paired |

*Every option counts the same toward your capstone — pick whichever fits your real work.* An MCP server can be a **small local script** (Python or Node) that Claude Code launches on your machine, or a **remote service** — either is a valid capstone. Start **read-only**, fewest useful operations, config included; prep is the self-paced *Extending Claude Code* module.

**Evidence — two things for every artifact:** an **impact note** in your own words (what it saves or improves — “before, this was all manual” is a fine story; numbers only if you have them), and a short **“how to use” README**. If it is something the team will pick up, also name the **teammate who will adopt it**.

**Your 8 minutes on Demo Day (max, per developer or paired entry):**

1. **Come on live** and share your screen.
2. **Introduce your artifact** — what it is and the problem it removes (~2 min).
3. **Practical demonstration** — run it on real work, live (~4 min).
4. **Questions & answers** from the room (~2 min).

**Done means:**

- ☐ one artifact you own, from the menu
- ☐ shown working at least once
- ☐ the evidence items
- ☐ Demo Day presentation delivered — counts toward **Framework Practitioner** (a governance-doc capstone still certifies)

**Stuck?** “Nothing to automate” is fine — ship a skill, doc, or connector. Scope too big — build the smallest useful version (start from the automation-asks list or your Lab 2 work). No adopter yet — recruit one teammate if the team will use it. That’s the point.
